Greetings, Sir!

The web application is supposed to be a Secret Menu for McDonald's. The home page lists three different food types (Meals, Sandwiches, Burgers) that work as links,

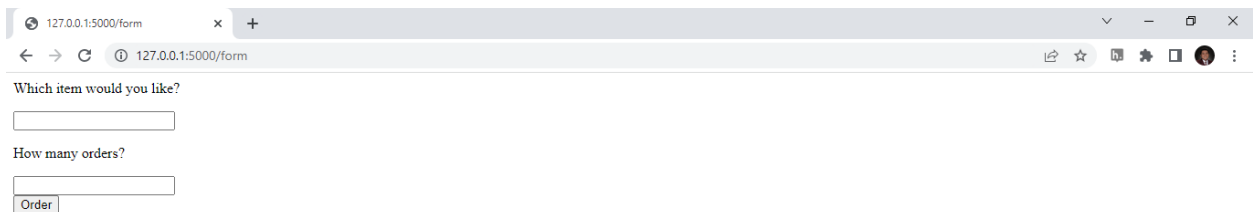

each redirecting to another list of three different food items,
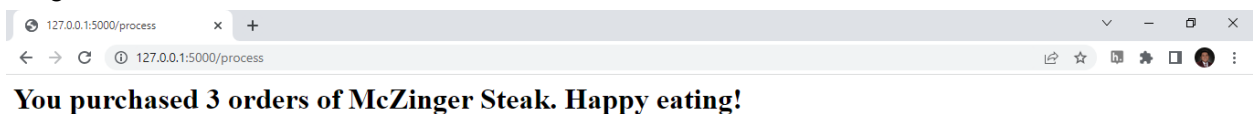

which further redirects to a page showing their details.

The fourth link in the home page leads to an order form.

Inputting strings and pressing the order button presents a report on the item and quantity that was ordered. I was unable to employ the mechanic that checks if the quantity entered is an integer, or if the food item entered matches the name.

Templating was employed only to some parts of the code, and there still are html codes in the python files which I was unable to translate into templates.

I was unable to employ static files and inheritance for the project.
